

Why Hybrid Meson Coupling to Two S-wave Mesons is Suppressed

Abstract

We introduce strong interaction selection rules for the two-body decay and production of hybrid and conventional mesons coupling to two S-wave hybrid or conventional mesons. The rules arise from symmetrization in states in the limit of non-relativistically moving quarks. The conditions under which the connected coupling of a hybrid to two S-wave hybrid or conventional mesons is suppressed are determined by the rules, and the nature of their breaking is indicated.

Certain vanishing decays were first noted in model calculations, and speculated to be of a common origin [1]. For example, for hybrids with a transverse electric constituent gluon (“TE hybrids”) [2], and hybrids arising in the limit where quarks move adiabatically (slowly) with respect to the gluonic degrees of freedom (“adiabatic hybrids”) in the flux-tube model [3], vanishing decays to orbital angular momentum $L = 0$ (S-wave) mesons were found. In both cases it was remarked that this was true for non-relativistically moving quarks with the same S-wave meson spatial wave functions and where the quark and antiquark in the hybrid have identical constituent masses. We show that the rules found in detailed dynamical models are included in

the novel, more general and model-independent statement of the rules provided by us. The exact conditions under which hybrid coupling to S-wave mesons vanishes are uncovered. In order to demonstrate vanishing coupling, we develop two-body decay and production selection rules for non-relativistically moving quarks. The rules will be found to apply to hybrid and conventional mesons coupling to two S-wave hybrid and conventional mesons, and arise due to symmetrization in the latter two states.

We shall be interested in strong decay and production $A \leftrightarrow BC$ processes in the rest frame of A. For simplicity we usually refer to the decay process $A \rightarrow BC$ (see Fig. 1), but the statements will be equally valid for the production process $A \leftarrow BC$. The states A, B and C contain a “valence” quark and antiquark and arbitrary gluonic content, i.e. they are conventional or hybrid mesons. In this letter we restrict to S-wave states B and C, which are either radially excited or ground states. Clearly conventional S-wave meson ground states B and C, which are henceforth mentioned in the examples, are most likely to be allowed by phase space. We assume that states B and C are identical in all respects except, in principle, their flavour, spin and their equal but opposite momenta $\mathbf{p}$ and $-\mathbf{p}$. Hence B and C have the same radial and gluonic excitation, as well as the same internal structure.

A given decay topology explicitly assumes a certain non-relativistic spin $S_{Q\bar{Q}}$ at each vertex. The physical applicability of the rules will hence be determined by the extent to which a given decay topology is believed to dominate decays. Models of meson decay usually assume either pair creation with spin $S_{Q\bar{Q}}$ or the exchange of a single quantum, either scalar confining, or colour Coulomb one gluon exchange (OGE) or transverse OGE (see Appendix B of ref. [4]). These all, in the non-relativistic limit, involve $S_{Q\bar{Q}} = 1$ pair creation and do not involve spin change for a forward moving quark¹. We shall analyse the implications of symmetrization for some of the model topologies in Figure 1, especially the connected topology 1.

The non-relativistic symmetrization selection rule and the conditions for vanishing hybrid couplings are clearly stated in the next section, where we perform a detailed derivation. In section 2 non-connected topologies are touched upon. Breaking of the rules and phenomenology are discussed in section 3.

1 Connected coupling

In this section we shall focus on topology 1, and shall follow the symmetrization arguments of ref. [5].

For the strong processes we consider the helicity amplitude for the connected decay is always

¹The only exception is for a forward moving quark interacting with a transverse gluon, where a spin 1 term contributes. The term is not considered in this letter.

Figure 1: Hybrid and conventional meson decay topologies. For each diagram, state A is on the left-hand side, and states B and C on the right-hand side. Quark flavours are labelled by Q , q and P . The “dots” indicate vertices where pair creation with spin $S_{Q\bar{Q}}$ is allowed.

the sum of two parts [5]:

$$\mathcal{A}_{tot}(\mathbf{p}) = \mathcal{C} \otimes \mathcal{F} \otimes \mathcal{S} \otimes \mathcal{L}(\mathbf{p}) + \mathcal{C}_{B \leftrightarrow C} \otimes \mathcal{F}_{B \leftrightarrow C} \otimes \mathcal{S}_{B \leftrightarrow C} \otimes \mathcal{L}_{B \leftrightarrow C}(\mathbf{p}) \quad (1)$$

Here we factored out the colour $\mathcal{C}$, flavour $\mathcal{F}$ and spin $\mathcal{S}$ overlaps, and the “remaining” overlap $\mathcal{L}$. $B \leftrightarrow C$ denotes the effect of formally exchanging labels that specify the states B and C. When we exchange the momentum $\mathbf{p}$ to $-\mathbf{p}$, it is equivalent to exchanging the labels $B \leftrightarrow C$ for every property in the wave function of the state except flavour, colour and spin, i.e. $\mathcal{L} \leftrightarrow \mathcal{L}_{B \leftrightarrow C}$ [5]. Hence, under $\mathbf{p} \rightarrow -\mathbf{p}$

$$\begin{aligned} \mathcal{A}_{tot}(\mathbf{p}) &\rightarrow \mathcal{C} \otimes \mathcal{F} \otimes \mathcal{S} \otimes \mathcal{L}(-\mathbf{p}) + \mathcal{C}_{B \leftrightarrow C} \otimes \mathcal{F}_{B \leftrightarrow C} \otimes \mathcal{S}_{B \leftrightarrow C} \otimes \mathcal{L}_{B \leftrightarrow C}(-\mathbf{p}) \\ &= \mathcal{C} \otimes \mathcal{F} \otimes \mathcal{S} \otimes \mathcal{L}_{B \leftrightarrow C}(\mathbf{p}) + \mathcal{C}_{B \leftrightarrow C} \otimes \mathcal{F}_{B \leftrightarrow C} \otimes \mathcal{S}_{B \leftrightarrow C} \otimes \mathcal{L}(\mathbf{p}) \\ &= fs \{ \mathcal{C}_{B \leftrightarrow C} \otimes \mathcal{F}_{B \leftrightarrow C} \otimes \mathcal{S}_{B \leftrightarrow C} \otimes \mathcal{L}_{B \leftrightarrow C}(\mathbf{p}) + \mathcal{C} \otimes \mathcal{F} \otimes \mathcal{S} \otimes \mathcal{L}(\mathbf{p}) \} = fs \mathcal{A}_{tot}(\mathbf{p}) \end{aligned} \quad (2)$$

We assumed that the colour structure of B and C are the same so that $\mathcal{C}_{B \leftrightarrow C} = \mathcal{C}$ [5]. Also $\mathcal{F}_{B \leftrightarrow C} \equiv f\mathcal{F}$ for the flavour scenarios we consider [5]. From the Appendix we see that $\mathcal{S}_{B \leftrightarrow C} = s\mathcal{S}$ where $s = (-1)^{S_A + S_B + S_C + S_{Q\bar{Q}}}$. Here S_A , S_B and S_C are the spins of states A, B and C. Until now we have referred to the helicity amplitude $\mathcal{A}_{tot}(\mathbf{p})$. Since its behaviour under $\mathbf{p} \rightarrow -\mathbf{p}$ is independent of total angular momentum projections, its behaviour remains the same for a linear combination of amplitudes with various total angular momentum projections, an example of which is a partial wave amplitude. By an abuse of notation we shall also call the partial wave amplitude “ $\mathcal{A}_{tot}(\mathbf{p})$ ”. Hence $\mathbf{p} \rightarrow -\mathbf{p}$ implies $\mathcal{A}_{tot}(\mathbf{p}) \rightarrow fs \mathcal{A}_{tot}(\mathbf{p})$. For decays where $fs = (-1)^{L+1}$, where L is the partial wave between B and C, we conclude that $\mathbf{p} \rightarrow -\mathbf{p}$ implies $\mathcal{A}_{tot}(\mathbf{p}) \rightarrow (-1)^{L+1} \mathcal{A}_{tot}(\mathbf{p})$. Since in L-wave under $\mathbf{p} \rightarrow -\mathbf{p}$ we have by analyticity that $\mathcal{A}_{tot}(\mathbf{p}) \rightarrow (-1)^L \mathcal{A}_{tot}(\mathbf{p})$, it follows that $\mathcal{A}_{tot}(\mathbf{p})$ vanishes. This is the desired result.

Now we shall find necessary and sufficient conditions for the requirement $fs = (-1)^{L+1}$. Since the B and C are identical (except for flavour and spin) they have the same parity, due to the fact that the parity of a state is fully determined by the intrinsic parities of the constituents and the orbital excitation between them, *not* by the spin of a state. We conclude that for a parity allowed process, the parity of state A is $P_A = (-1)^L$. We shall see below that $fs = (-1)^{S_A+S_{Q\bar{Q}}}C_A^0$. For a neutral state, C_A^0 is just the C-parity of the state. For charged states (with no C-parity), we assume that at least one of the states in the isomultiplet it belongs to has a well-defined C-parity, denoted by C_A^0 . We now have

$$P_A = (-1)^L = -(-1)^{L+1} = -fs = (-1)^{S_A+S_{Q\bar{Q}}+1}C_A^0 \quad (3)$$

Defining the action of charge conjugation on a spin 0 state $Q\bar{q}$ as $C(Q\bar{q}) = c q\bar{Q}$, where c is an intrinsic charge conjugation, and noting that $C((Q\bar{q})^*) = -c (q\bar{Q})^*$ for a spin 1 state $(q\bar{Q})^*$, we now show for various flavour scenarios that $fs = (-1)^{S_A+S_{Q\bar{Q}}}C_A^0$.

Category I: For a connected decay of the type $Q\bar{Q} \rightarrow Q\bar{q} q\bar{Q}$, $Q\bar{q} (q\bar{Q})^*$, $(Q\bar{q})^* (q\bar{Q})^*$ ($Q \neq q$), states B and C are not in general eigenfunctions of charge conjugation. However, the linear combinations $Q_C \equiv \frac{1}{\sqrt{2}}(|Q\bar{q}\rangle C |q\bar{Q}\rangle)$ (spin 0) and $Q_C^* \equiv \frac{1}{\sqrt{2}}(|(Q\bar{q})^*\rangle C |(q\bar{Q})^*\rangle)$ (spin 1) have charge conjugation cC and $-cC$ respectively. In addition, in $Q\bar{Q} \rightarrow Q\bar{q} q\bar{Q}$ there is no flavour symmetry on exchange $B \leftrightarrow C$, since one of the diagrams vanishes. As we shall see, this is corrected by considering decays into the eigenstates of charge conjugation Q_C and Q_C^* . We can decompose $Q\bar{q} (q\bar{Q})^* = \frac{1}{2}(Q_+Q_+^* - Q_-Q_-^* - Q_+Q_-^* + Q_-Q_+^*)$ into parts with proper C symmetry. The same can be done for $Q\bar{q} q\bar{Q}$ and $(Q\bar{q})^* (q\bar{Q})^*$.

Noting that Q_C and Q_C^* differ only in spin, their flavour behaviour is identical, so we only discuss the flavour behaviour of Q_C . $Q\bar{Q} \rightarrow Q_+Q_+$, Q_-Q_- are trivially invariant under $B \leftrightarrow C$, so that $f = 1$. Also, for

$$Q\bar{Q} \rightarrow Q_+Q_- : \langle Q\bar{Q} | Q_+Q_- \rangle = -\frac{1}{2} \quad Q\bar{Q} \rightarrow Q_-Q_+ : \langle Q\bar{Q} | Q_-Q_+ \rangle = \frac{1}{2} \quad (4)$$

and hence $f = -1$ for $Q\bar{Q} \rightarrow Q_+Q_-$, Q_-Q_+ .

For Q_+Q_+ , Q_-Q_- , $Q_+^*Q_+^*$, $Q_-^*Q_-^*$, $Q_+Q_-^*$, $Q_-Q_+^*$ states B and C we have $C_{B+C} = 1$ and by conservation of charge conjugation $C_A = 1$. For the first four combinations $f = 1$ so that $fs = +(-1)^{S_A+S_{Q\bar{Q}}} = (-1)^{S_A+S_{Q\bar{Q}}}C_A$. For the latter two combinations $f = -1$ and hence $fs = -(-1)^{S_A+1+S_{Q\bar{Q}}} = (-1)^{S_A+S_{Q\bar{Q}}}C_A$.

For Q_+Q_- , Q_-Q_+ , $Q_+^*Q_-^*$, $Q_-^*Q_+^*$, $Q_+Q_+^*$, $Q_-Q_-^*$ states B and C we have $C_{B+C} = -1$ which implies that $C_A = -1$. For the first four combinations $f = -1$ so that $fs = -(-1)^{S_A+S_{Q\bar{Q}}} = (-1)^{S_A+S_{Q\bar{Q}}}C_A$. For the latter two combinations $f = 1$ and hence $fs = +(-1)^{S_A+1+S_{Q\bar{Q}}} = (-1)^{S_A+S_{Q\bar{Q}}}C_A$.

Examples: $s\bar{s} \rightarrow K\bar{K}, K\bar{K}^*, K^*\bar{K}^*$; $c\bar{c} \rightarrow D\bar{D}, D\bar{D}^*, D^*\bar{D}^*, D_s\bar{D}_s, D_s\bar{D}_s^*, D_s^*\bar{D}_s^*$;
 $b\bar{b} \rightarrow B\bar{B}, B\bar{B}^*, B^*\bar{B}^*, B_s\bar{B}_s, B_s\bar{B}_s^*, B_s^*\bar{B}_s^*$; $\Pi^0 \rightarrow \pi^+\pi^-, \pi^\pm\rho^\mp, \rho^+\rho^-$;
 $\Omega \rightarrow \pi^+\pi^-, \pi^\pm\rho^\mp, \rho^+\rho^-$,

where e.g. $K\bar{K}$ includes K^+K^- and $K^0\bar{K}^0$, Π^0 denotes a state with flavour $u\bar{u} - d\bar{d}$ and Ω denotes $u\bar{u} + d\bar{d}$.

Category II: If we assume isospin symmetry for u, d quarks, then for G-parity eigenstates $G_A = G_B G_C$ by G-parity conservation. Since $G_H = C_H^0(-1)^{I_H}$, we obtain $C_A^0 C_B^0 C_C^0 = (-1)^{I_A+I_B+I_C}$. It can, however, be verified that $f = (-1)^{I_A+I_B+I_C}$ for decays involving u, d quarks (see the Appendix of ref. [5]). This continues to hold [5] for $Q\bar{Q} \rightarrow Q\bar{Q} Q\bar{Q}$ with $Q = s, c, b$ (where $f = 1$).

For $Q\bar{Q} Q\bar{Q}$, $(Q\bar{Q})^* (Q\bar{Q})^*$ states B and C we have $C_B^0 C_C^0 = 1$ so that $C_A^0 = (-1)^{I_A+I_B+I_C}$ and hence $f s = (-1)^{I_A+I_B+I_C} (-1)^{S_A+S_B+S_C+S_{Q\bar{Q}}} = (-1)^{S_A+S_{Q\bar{Q}}} C_A^0$.

For $Q\bar{Q} (Q\bar{Q})^*$ states B and C we have $C_B^0 C_C^0 = -1$ so that $C_A^0 = (-1)^{I_A+I_B+I_C+1}$ and hence $f s = (-1)^{I_A+I_B+I_C} (-1)^{S_A+S_B+S_C+S_{Q\bar{Q}}} = (-1)^{S_A+S_{Q\bar{Q}}} C_A^0$.

Examples: $\Omega, s\bar{s} \rightarrow \eta\eta, \eta'\eta, \eta\omega, \eta'\omega, \eta\phi, \eta'\phi, \pi^0\pi^0, \pi^0\rho^0, \rho^0\rho^0, \omega\omega, \phi\phi$;
 $\Pi^0 \rightarrow \pi^0\eta, \pi^0\eta', \pi^0\omega, \rho^0\eta, \rho^0\eta', \rho^0\omega$;
 $\Pi^\pm \rightarrow \pi^\pm\pi^0, \pi^\pm\eta, \pi^\pm\eta', \pi^\pm\omega, \pi^\pm\rho^0, \rho^\pm\pi^0, \rho^\pm\rho^0, \rho^\pm\eta, \rho^\pm\eta', \rho^\pm\omega$.

Non-relativistic Symmetrization Selection Rule: *Connected decay and production of $C_A^0 P_A = (-1)^{S_A+S_{Q\bar{Q}}+1}$ hybrid and conventional mesons with quark content $Q\bar{Q}$, where S_A is the spin of the state and $S_{Q\bar{Q}}$ the spin of the created or annihilated pair, coupling to S-wave hybrid or conventional mesons which are identical in all respects, except possibly flavour and spin, vanish for non-relativistic quarks. In the case of isospin symmetry for topologies involving only u, d quarks the same rule applies in addition to states A with quark content $Q\bar{q}$.*

If $S_{Q\bar{Q}} = 1$ as models suggest, the condition that $C_A^0 P_A = (-1)^{S_A+S_{Q\bar{Q}}+1}$ is fulfilled for $J_A^{P_A C_A^0} = (0, 1, 2, \dots)^{\pm\pm}$ with $S_A = 0$ and $J_A^{P_A C_A^0} = (0, 1, 2, \dots)^{\pm\mp}$ with $S_A = 1$.

For conventional mesons, $C_A^0 = (-1)^{L_A+S_A}$ and $P_A = (-1)^{L_A+1}$, so that $C_A^0 P_A = (-1)^{S_A+1}$. So only spin 0 pair creation, usually thought to be highly suppressed, gives vanishing amplitudes. This may be related to the phenomenological success [6] of decay models fitting experiment with spin 1 pair creation, although theoretical considerations independently motivate spin 1 pair creation. $J^P = 1^-$ transverse magnetic constituent gluons yield 1^{+-} , $(0, 1, 2)^{++}$ hybrids (“TM hybrids”), which have identical spin structure to their conventional orbitally excited meson J^{PC} partners, so their spin 0 decays vanish, but not their spin 1 decays, consistent with covariant oscillator quark model calculations which find non-zero TM hybrid decays to S-wave mesons for spin 1 pair creation [7]. Moreover, ref. [8] finds $1^{-+} \rightarrow \rho\pi = 300$ MeV, with $S_A = 0$ quarks and spin 1 pair creation in the non-relativistic approximation.

If we assume spin 1 pair creation to be dominant, $P_A = (-1)^{S_A+S_{Q\bar{Q}}+1} C_A^0$ is satisfied for

adiabatic hybrids² with $J_A^{P_A C_A^0} = (0, 1, 2)_1^{-+}, 1_0^{--}, (0, 1, 2)_1^{+-}, 1_0^{++}$ and for the $J^P = 1^+$ TE hybrids $(0, 1, 2)_1^{-+}, 1_0^{--}$. Note that the latter hybrids have the same spin structure as their adiabatic limit J^{PC} partners. Hence,

Connected decay and production of adiabatic hybrids coupling to S-wave conventional mesons which are identical in all respects, except possibly flavour and spin, vanish for non-relativistic quarks with spin 1 pair creation. The quark content of the hybrid is either $Q\bar{Q}$ or $Q\bar{q}$, where the latter is only relevant to topologies involving only u, d quarks where isospin symmetry is assumed.

Vanishing decay of adiabatic hybrids to S-wave mesons via spin 1 pair creation is confirmed in the flux-tube model [3, 9] and for TE hybrids³ in refs. [2, 10, 11, 12]. It was historically surprising that vanishing decays occur in models motivated by both the strong and weak coupling limits of QCD. We have shown that this is because the decays have the same spin structure. TE and adiabatic hybrids can have connected decay via spin 0 pair creation, although in the case of $0^{+-}, 1^{-+}, 2^{+-} \rightarrow$ identical $J = 0$ states we know [5] that the decays vanish by the symmetrization rules of ref. [5]. TE and adiabatic hybrids with non-exotic J^{PC} have the opposite spin S_A to their conventional meson partners. It is hence clear why vanishing decays with $P_A = (-1)^{S_A+S_{Q\bar{Q}}+1}C_A^0$ arise *either* for hybrids *or* mesons, depending on $S_{Q\bar{Q}}$.

2 Non-connected coupling

Except for the decays $\Pi^\pm \rightarrow \pi^\pm \pi^0$, $\rho^\pm \pi^0$, $\pi^\pm \rho^0$, $\rho^\pm \rho^0$ all decays listed in the previous section have contributions from non-connected topologies 2 and 3.

Category II non-relativistic symmetrization arguments can be applied to the non-connected topology 2 yielding no new vanishing decays not included amongst those listed for the same flavour topology in ref. [5].

Symmetrization arguments can be applied for topologies 3 to yield vanishing decays only in specific models. In other models, the diagrams with $B \leftrightarrow C$ are not topologically distinct, making it impossible to proceed. No phenomenologically successful models have to the best of our knowledge been proposed utilizing topologies 3. In the light of this, we do not develop symmetrization arguments further.

²The listed J^{PC} are those of the lowest lying hybrids in the E_u flux-tube representation on the hypercubic lattice [17]. For spin 1 pair creation, $P_A = (-1)^{S_A+S_{Q\bar{Q}}+1}C_A^0$ is also satisfied for energetically higher lying hybrids in the $E_u, A_{1u}, A_{2u}, B_{1u}$ and B_{2u} representations. This is independent of the orbital and radial excitation of the $Q\bar{Q}$, and fully determined by the flux-tube representation, as can most easily be seen in the flux-tube model, where $P_A = (-1)^{S_A+S_{Q\bar{Q}}+1}C_A^0$ is equivalent to a constraint on the flux-tube degrees of freedom [18, Eqns. A1 - A2].

³Ref. [12] claims in a specific model that the results survive even after the lifting of the assumption of non-relativistic quark motion.

3 Phenomenology

There are considerably more sources of breaking of the non-relativistic symmetrization selection rules than for those discussed in ref. [5]. As we shall see, breaking of selection rules is likely to be the smallest for decays of $c\bar{c}$ and $b\bar{b}$ states. Breaking of rules arise due to:

- Differing on-shell wave functions for B and C: Final states with different internal structure would break the symmetrization selection rules. There is, however, no explicit breaking due to differences in energy or mass [5]. Corrections due to differing spatial wave functions for B and C due to spin-dependent forces are found to be given by $(R_B^2 - R_C^2)^2 / (R_B^2 + R_C^2)^2$ in models with harmonic oscillator wave functions [8, 9, 13], where R is the radius of the state. This ratio ranges from approximately 20% for $\rho\pi$ [9] to 4% for $D^*\bar{D}$ or 1% for $B^*\bar{B}$ to 0% for $D\bar{D}, D^*\bar{D}^*, B\bar{B}, B^*\bar{B}^*$ [14]. Topology 1 decay widths for $c\bar{c}$ and $b\bar{b}$ adiabatic hybrids to S-wave mesons of respectively 1 – 10 MeV and 1 – 4 MeV have been predicted for spin 1 pair creation [14].

- Differing off-shell wave functions for B and C: Breaking of the rules could be more substantial [5, 9] than for on-shell states, enabling off-shell meson exchange as a potentially significant hybrid production mechanism, e.g in $\pi N \rightarrow 1^{-+} N$ with ρ exchange.

- Different spin assignments and mixing: The spin assignments of unmixed hybrid and conventional mesons assume that the adiabatic limit survives even for light quark mesons. This is motivated by the success of the non-relativistic quark model. Also, a simulation in the flux-tube model indicates that “mixing between [adiabatic] surfaces is of the order of 1% or less” even for light quark systems [16]. Moreover, constituent gluon models usually find small mixing between hybrid and conventional mesons [2, 12].

- Relativistic effects: Notwithstanding the successes of the non-relativistic quark model, there is no decay of current interest for which the non-relativistic assumption is compelling. Even for a $b\bar{b}$ state decaying via s-quark pair creation, the s-quark is not manifestly non-relativistic. If fully relativistic QCD sum rule calculations are a guide, u, d quark 1^{-+} has a width of 10 – 600 MeV to $\rho\pi$ and 8 – 300 MeV to K^*K [15]. These large uncertainties in widths unfortunately leave the size of relativistic effects unresolved.

Decays suppressed by selection rules in a given topology can receive other contributions from:

- ◊ Other quark topologies: Of most interest here is the additional contribution of non-connected topologies to a suppressed connected topology. If non-connected decays of hybrids are similar to that of mesons, they are expected to be suppressed, less than $\mathcal{O}(10^{-1} \text{ MeV})$ for $c\bar{c}$ and $\mathcal{O}(10^{-2} \text{ MeV})$ for $b\bar{b}$ states. If QCD sum rule calculations are a guide, u, d quark hybrid 1^{-+} has a $\eta\pi$ width of 0.3 MeV and a $\eta'\pi$ width of 3 – 4 MeV [15], suggesting the suppression of non-connected hybrid decays.

- ◊ Different decay processes to those in Figure 1 and pair creation with $S_{Q\bar{Q}} \neq 1$, as discussed

before.

It seems reasonable to assume that decays of hybrid $c\bar{c}$ to $D\bar{D}, D^*\bar{D}, D^*\bar{D}^*, D_s\bar{D}_s, D_s^*\bar{D}_s, D_s^*\bar{D}_s^*$ and hybrid $b\bar{b}$ to $B\bar{B}, B^*\bar{B}, B^*\bar{B}^*, B_s\bar{B}_s, B_s^*\bar{B}_s, B_s^*\bar{B}_s^*$ are suppressed. Moreover, hybrid $0^{+-}, 1^{-+}, 2^{+-}, 3^{-+}, \dots$ $c\bar{c} \rightarrow D\bar{D}, D_s\bar{D}_s$ and $b\bar{b} \rightarrow B\bar{B}, B_s\bar{B}_s$ vanish by CP conservation. Since heavy hybrid states have consistently been predicted below the $(L=0) + (L=1)$ threshold [17], this implies the tantalizing prospect of narrow $c\bar{c}$ and $b\bar{b}$ hybrids.

The principle of symmetrization applied to non-relativistic quarks has been shown to underpin the suppression of hybrid coupling to S-wave states for spin 1 pair creation, binding together numerous model calculations.

Discussions with M.C. Birse, F.E. Close, N. Isgur, C. Michael, O. Pène, J.C. Raynal, M.R. Pennington, P. Sutton and motivation from S.-F. Tuan are acknowledged.

A Appendix: Spin Overlaps

The spin state is

$$|H\rangle = \sum_{h\bar{h}} H_{h\bar{h}} |h\rangle |\bar{h}\rangle \quad \text{where} \quad H_{h\bar{h}} = \langle S_H S_H^z | \frac{1}{2} h \frac{1}{2} - \bar{h} \rangle (-1)^{\frac{1}{2} - \bar{h}} \quad (5)$$

and $|\frac{1}{2}\rangle = \uparrow$, $|\frac{1}{2}\rangle = \downarrow$, $|\frac{1}{2}\rangle = \bar{\downarrow}$ and $|\frac{1}{2}\rangle = -\bar{\uparrow}$. This just yields the usual $S_H = 1$ spin $\uparrow \bar{\uparrow}$, $\frac{1}{\sqrt{2}}(\uparrow \bar{\downarrow} + \downarrow \bar{\uparrow})$, $\downarrow \bar{\downarrow}$ for $S_H^z = 1, 0, -1$ and $\frac{1}{\sqrt{2}}(\uparrow \bar{\downarrow} - \downarrow \bar{\uparrow})$ for $S_H = 0$. The pair creation or annihilation operator is $\sum_{h\bar{h}} \langle S_{Q\bar{Q}} S_{Q\bar{Q}}^z | \frac{1}{2} h \frac{1}{2} - \bar{h} \rangle (-1)^{\frac{1}{2} - \bar{h}} |h\rangle |\bar{h}\rangle$. The advantage of this representation for spin is that a spin 0 operator is $\frac{1}{\sqrt{2}} \delta_{h\bar{h}}$ which is a multiple of the identity matrix. So spin 0 interactions on forward moving quark lines are trivial. The spin 1 operators are just related to the Pauli matrices as $-\frac{1}{2}(\sigma_x + i\sigma_y)$ for $S_{Q\bar{Q}}^z = 1$, $\frac{1}{\sqrt{2}}\sigma_z$ for $S_{Q\bar{Q}}^z = 0$ and $\frac{1}{2}(\sigma_x - i\sigma_y)$ for $S_{Q\bar{Q}}^z = -1$.

For the connected decay of topology 1 the spin overlap $\mathcal{S}$ is

$$\begin{aligned} & \sum_{a\bar{a}b} A_{a\bar{a}} B_{a\bar{b}} \langle S_{Q\bar{Q}} S_{Q\bar{Q}}^z | \frac{1}{2} b \frac{1}{2} - \bar{b} \rangle (-1)^{\frac{1}{2} - \bar{b}} C_{b\bar{a}} \\ &= \sum_{a\bar{a}b\bar{b}} \langle S_A S_A^z | \frac{1}{2} a \frac{1}{2} - \bar{a} \rangle \langle S_B S_B^z | \frac{1}{2} a \frac{1}{2} - \bar{b} \rangle \langle S_{Q\bar{Q}} S_{Q\bar{Q}}^z | \frac{1}{2} b \frac{1}{2} - \bar{b} \rangle \langle S_C S_C^z | \frac{1}{2} b \frac{1}{2} - \bar{a} \rangle \end{aligned} \quad (6)$$

which can easily be shown to give the sign $s = (-1)^{S_A + S_B + S_C + S_{Q\bar{Q}}}$ under $B \leftrightarrow C$.
